Understanding Cassandra queries

Examples

```
CREATE TABLE movies (
   title text,
   director text,
   year int,
   genre text,
   PRIMARY KEY (title, director, year);
```

N1

(A, d1, 2000,...) (A, d1, 2010,...) (A, d1, 2015,...) (A, d2, 1999,...) (A, d3, 1998,...) (A, d4, 2014,...) (B, d5, 1970,...) N2

(C, d1, 2000,...) (C, d2, 2020...)

(D, d6, 1999...)

• • •

Inside each partition, ordered with respect to the partition key and the clustering column values (order by title, director, year)

Queries can be executed if

- 1. It is possible to locate the nodes storing the rows to be retrieved
- 2. In each node, the rows to be retrieved are sequentially stored

```
CREATE TABLE movies (
   title text,
   director text,
   year int,
   genre text,
   PRIMARY KEY (title, director, year);
```

```
SELECT*
FROM movies
WHERE title = 'A' AND
director= 'd1' AND
year > 2000
```

N1

(A, d1, 2000,...) (A, d1, 2010,...) (A, d1, 2015,...) (A, d2, 1999,...) (A, d3, 1998,...) (A, d4, 2014,...) (B, d5, 1970,...) ... (C, d1, 2000,...) (C, d2, 2020,...) (D, d6, 1999,...) ...

N2

The query is **ADMITTED** because

- 1. It is possible to locate the nodes storing the rows to be retrieved (N1)
- 2. In N1, the rows to be retrieved are sequentially stored (two sequential tuples, in blue)

```
CREATE TABLE movies (
   title text,
   director text,
   year int,
   genre text,
   PRIMARY KEY (title, director, year);
```

```
SELECT*
FROM movies
WHERE title = 'A' AND
year > 2000
```

N1

(A, d1, 2000,...) (A, d1, 2010,...) (A, d1, 2015,...) (A, d2, 1999,...) (A, d3, 1998,...) (A, d4, 2014,...) (B, d5, 1970,...) ... (C, d1, 2000,...) (C, d2, 2020,...) (D, d6, 1999, ...) ... The query is **NON ADMITTED** because

- 1. It is possible to locate the nodes storing the rows to be retrieve (N1)
- 2. But, in N1 the rows to be retrieved are NOT sequentially stored (three tuples, in blue)

Conditions that guarantee the desired behaviour

- The WHERE clause must contain an equality-based selection condition on each attribute of the partition key
 - IN clause is also allowed (a set of nodes is identified)
 - The system is able to identify the nodes contributing to the result
- The WHERE clause can contain selection conditions over any prefix of the clustering column list, as defined in the primary key
 - If more than one clustering column exist, range restrictions are allowed only on the last clustering column being restricted in the WHERE clause
 - On the identified nodes, rows to be returned must be sequentially stored
